Abraded and impure iron was therefore a serious fire risk. It was not until the 2 mm thick steel plate construction developed in the 1870s that the demand for iron was covered. Most of the areas where iron was used in civil engineering were urban areas. Coal was burned in all iron burning structures. The risk of fire was a serious one in any enclosed place. To lessen the risk, the open layout of plants was begun. With the decline of the iron trade, the risk of fires further decreased. The new technology and more stringent standards made it possible to eliminate this risk and it was finally eliminated in the 1960s. Early civil engineers were less concerned about fire as a safety risk. They only had to consider water damage and simple structural failures. As the industry expanded, the risk of fires increased as the fire brigade was not sufficient to cover the larger cities in 1870. Concrete could not be used in these areas because the risk of fire was too high. The fire brigade, with the ever growing and more important works, was not sufficient to handle a fire in a large industrial complex. As the industry expanded, the demand for iron increased and the risks increased as well. The city walls and towers were built during this period. These were large structures as the risks of fire were high. The factory was difficult to access as a large number of firefighters and fire engines were needed to control a large fire. The demand for iron grew until the demand was enough to cover every large industry in the 1970s. The fire brigade was still not sufficient to handle every city in the world. Although many were industrialized in Europe during the 20th century, the risks of fire were also high in these countries. In addition to the growth of the iron business, the demands of the steel industry grew. As the steel business required more and more iron, the risks of fire increased. The case was the same in North America. The steel industry took off in the 1960s. The

This article reports on the qualitative phase of a study into the development and evaluation of an instrument to assess clinical interview skills of student nurses. The interview was a key clinical skill in the placement and continuing education of student nurses. An instrument was developed from the literature on assessment of clinical skills and interview techniques and feedback from qualified clinicians. It was then refined and used to compare the clinical skills of student nurses. The qualitative phase of the study included open questions asked of student nurses and a general discussion of the student nurses' performance. The instrument was a major part of the student 3e33713323
